## Review of Local Optimization

## Review from Last Time

- A basic block is a series of IR instructions where
- there is one entry point into the basic block, and
- there is one exit point out of the basic block.
- Intuitively, a block of IR instructions that all must execute as a unit.
- A control-flow graph (CFG) is a graph of the basic blocks of a function.
- Each edge in a CFG corresponds to a possible flow of control through the program.

## Review from Last Time

- A local optimization is an optimization of IR instructions within a single basic block.
- We saw five examples of this:
- Common subexpression elimination.
- Copy propagation.
- Dead code elimination.
- Arithmetic simplification.
- Constant folding.

## Review from Last Time

- Last time, we defined two analyses used in our optimizations.
- Available expressions: Track what variables are assigned which expressions.
- Compute by walking forward across the values in a basic block.
- Live variables: Track what variables will eventually be used.
- Compute by walking backward across the values in a basic block.

## Available Expressions

$$
\begin{gathered}
a=b ; \\
c=b ; \\
d=a+b ; \\
e=a+b ; \\
d=b ; \\
f=a+b ;
\end{gathered}
$$

## Available Expressions

$$
\begin{aligned}
& \text { \{ \} } \\
& \mathrm{a}=\mathrm{b} \text {; } \\

## Another View of Local Analyses

## Another View of Local Analyses

## Another View of Local Analyses

## Another View of Local Analyses

## Another View of Local Analyses

## Another View of Local Optimization

- In local optimization, we want to reason about some property of the runtime behavior of the program.
- Could we run the program and just watch what happens?
- Idea: Redefine the semantics of our programming language to give us information about our analysis.

## Properties of Local Analysis

- The only way to find out what a program will actually do is to run it.
- Problems:
- The program might not terminate.
- The program might have some behavior we didn't see when we ran it on a particular input.
- However, this is not a problem inside a basic block.
- Basic blocks contain no loops.
- There is only one path through the basic block.

## Assigning New Semantics

- Example: Available Expressions
- Redefine the statement $\mathbf{a}=\mathbf{b}+\mathbf{c}$ to mean "a now holds the value of $\mathbf{b}+\mathbf{c}$, and any variable holding the value $\mathbf{a}$ is now invalid."
- Run the program assuming these new semantics.
- Treat the optimizer as an interpreter for these new semantics.

## Information for a Local Analysis

- What direction are we going?
- Sometimes forward (available expressions)
- Sometimes backward (liveness analysis)
- How do we update information after processing a statement?
- What are the new semantics?
- What information do we know initially?

## Formalizing Local Analyses

- Define an analysis of a basic block as a quadruple (D, V, F, I) where
- D is a direction (forwards or backwards)
- $\mathbf{V}$ is a set of values the program can have at any point.
- $\mathbf{F}$ is a family of transfer functions defining the meaning of any expression as a function $f: \mathbf{V} \rightarrow \mathbf{V}$.
- $\mathbf{I}$ is the initial information at the top (or bottom) of a basic block.

## Available Expressions

$$
\begin{gathered}
a=b ; \\
c=b ; \\
d=a+b ; \\
e=a+b ; \\
d=b ; \\
f=a+b ;
\end{gathered}
$$

## Available Expressions

$$
\begin{aligned}
& \text { \{ \} } \\
& \mathrm{a}=\mathrm{b} \text {; } \\
& \text { c = b; } \\
& \mathrm{d}=\mathrm{a}+\mathrm{b} \text {; } \\
& \mathrm{e}=\mathrm{a}+\mathrm{b} \text {; } \\
& \mathrm{d}=\mathrm{b} \text {; } \\
& \mathrm{f}=\mathrm{a}+\mathrm{b} \text {; }
\end{aligned}
$$

## Available Expressions

$$
\begin{gathered}

\end{aligned}
$$

## Available Expressions

- Direction: Forward
- Domain: Sets of expressions assigned to variables.
- Transfer functions: Given a set of variable assignments $V$ and statement $\mathbf{a}=\mathbf{b}+\mathbf{c}$ :
- Remove from $V$ any expression containing a as a subexpression.
- Add to $V$ the expression $\mathbf{a}=\mathbf{b}+\mathbf{c}$.
- Initial value: Empty set of expressions.

# Liveness Analysis

& \text { \{ b, d, e \} } \\
& \mathrm{f}=\mathrm{e} \text {; } \\
& \text { \{ b, d \} }
\end{aligned}
$$

## Liveness Analysis

- Direction: Backwards
- Domain: Sets of variables.
- Transfer function: Given a set of variables $V$ and statement $\mathbf{a}=\mathbf{b}+\mathbf{c}$ :
- Remove a from $V$ (any previous value of $\mathbf{a}$ is now dead.)
- Add $\mathbf{b}$ and $\mathbf{c}$ to $V$ (any previous value of $\mathbf{b}$ or $\mathbf{c}$ is now live.)
- Formally: $\mathrm{f}_{\mathrm{a}=\mathrm{b}+\mathrm{c}}(V)=(V-\{\mathbf{a}\}) \cup\{\mathbf{b}, \mathbf{c}\}$
- Initial value: Depends on semantics of language.

## Running Local Analyses

- Given an analysis ( $\mathbf{D}, \mathbf{V}, \mathbf{F}, \mathbf{I}$ ) for a basic block.
- Assume that $\mathbf{D}$ is "forward;" analogous for the reverse case.
- Initially, set OUT[entry] to I.
- For each statement $\mathbf{s}$, in order:
- Set IN[s] to OUT[prev], where prev is the previous statement.
- Set OUT[s] to $\mathrm{f}_{\mathrm{s}}(\operatorname{IN}[\mathbf{s}])$, where $\mathrm{f}_{\mathrm{s}}$ is the transfer function for statement $\mathbf{s}$.

## Global Optimizations

## Global Analysis

- A global analysis is an analysis that works on a control-flow graph as a whole.
- Substantially more powerful than a local analysis.
- (Why?)
- Substantially more complicated than a local analysis.
- (Why?)

## Local vs. Global Analysis

- Many of the optimizations from local analysis can still be applied globally.
- We'll see how to do this later today.
- Certain optimizations are possible in global analysis that aren't possible locally:
- e.g. code motion: Moving code from one basic block into another to avoid computing values unnecessarily.
- We'll explore three analyses in detail:
- Global dead code elimination.
- Global constant propagation.
- Partial redundancy elimination.

## Global Dead Code Elimination

- Local dead code elimination needed to know what variables were live on exit from a basic block.
- This information can only be computed as part of a global analysis.
- How do we modify our liveness analysis to handle a CFG?

$$

## Major Changes, Part II

- In a local analysis, there is only one possible path through a basic block.
- In a global analysis, there may be many paths through a CFG.
- May need to recompute values multiple times as more information becomes available.
- Need to be careful when doing this not to loop infinitely!
- (More on that later)

## CFGs with Loops

- Up to this point, we've considered loop-free CFGs, which have only finitely many possible paths.
- When we add loops into the picture, this is no longer true.
- Not all possible loops in a CFG can be realized in the actual program.

## CFGs with Loops

- Up to this point, we've considered loop-free CFGs, which have only finitely many possible paths.
- When we add loops into the picture, this is no longer true.
- Not all possible loops in a CFG can be realized in the actual program.

## CFGs with Loops

- Up to this point, we've considered loop-free CFGs, which have only finitely many possible paths.
- When we add loops into the picture, this is no longer true.
- Not all possible loops in a CFG can be realized in the actual program.
- Sound approximation: Assume that every possible path through the CFG corresponds to a valid execution.
- Includes all realizable paths, but some additional paths as well.
- May make our analysis less precise (but still sound).
- Makes the analysis feasible; we'll see how later.

## CFGs With Loops

## CFGs With Loops

## CFGs With Loops

## Major Changes, Part III

- In a local analysis, there is always a welldefined "first" statement to begin processing.
- In a global analysis with loops, every basic block might depend on every other basic block.
- To fix this, we need to assign initial values to all of the blocks in the CFG.

## Summary of Differences

- Need to be able to handle multiple predecessors/successors for a basic block.
- Need to be able to handle multiple paths through the control-flow graph, and may need to iterate multiple times to compute the final value (but the analysis still needs to terminate!)
- Need to be able to assign each basic block a reasonable default value for before we've analyzed it.

## Global Liveness Analysis

- Initially, set $\operatorname{IN}[\mathbf{s}]=\{ \}$ for each statement $\mathbf{s}$.
- Set IN[exit] to the set of variables known to be live on exit (language-specific knowledge).
- Repeat until no changes occur:
- For each statement $\mathbf{s}$ of the form $\mathbf{a}=\mathbf{b}+\mathbf{c}$, in any order you'd like:
- Set OUT[s] to set union of IN[p] for each successor $\mathbf{p}$ of $\mathbf{s}$.
- Set IN[s] to (OUT[s] - a) $\cup\{\mathbf{b}, \mathbf{c}\}$.
- Yet another fixed-point iteration!

## Why Does This Work?

- To show correctness, we need to show that
- the algorithm eventually terminates, and
- when it terminates, it has a sound answer.
- Termination argument:
- Once a variable is discovered to be live during some point of the analysis, it always stays live.
- Only finitely many variables and finitely many places where a variable can become live.
- Soundness argument (sketch):
- Each individual rule, applied to some set, correctly updates liveness in that set.
- When computing the union of the set of live variables, a variable is only live if it was live on some path leaving the statement.

## Theory to the Rescue

- Building up all of the machinery to design this analysis was tricky.
- The key ideas, however, are mostly independent of the analysis:
- We need to be able to compute functions describing the behavior of each statement.
- We need to be able to merge several subcomputations together.
- We need an initial value for all of the basic blocks.
- There is a beautiful formalism that captures many of these properties.

## Meet Semilattices

- A meet semilattice is a ordering defined on a set of elements.
- Any two elements have some meet that is the largest element smaller than both elements.
- There is a unique top element, which is larger than all other elements.
- Intuitively:
- The meet of two elements represents combining information from two elements.
- The top element element represents "no information yet" or "the least conservative possible answer."

## Meet Semilattices for Liveness

## Formal Definitions

- A meet semilattice is a pair ( $D, \Lambda$ ), where
- D is a domain of elements.
- $\wedge$ is a meet operator that is
- idempotent: $\mathrm{x} \wedge \mathrm{x}=\mathrm{x}$
- commutative: $\mathrm{x} \wedge \mathrm{y}=\mathrm{y} \wedge \mathrm{x}$
- associative: $(x \wedge y) \wedge z=x \wedge(y \wedge z)$
- If $x \wedge y=z$, we say that $z$ is the meet or (greatest lower bound) of $x$ and $y$.
- Every meet semilattice has a top element denoted $\top$ such that $\top \wedge x=x$ for all $x$.

## An Example Semilattice

- The set of natural numbers and the max function.
- Idempotent
- $\max \{\mathrm{a}, \mathrm{a}\}=\mathrm{a}$
- Commutative
- $\max \{a, b\}=\boldsymbol{\operatorname { m a x }}\{\mathrm{b}, \mathrm{a}\}$
- Associative
- $\max \{\mathrm{a}, \boldsymbol{\operatorname { m a x }}\{\mathrm{b}, \mathrm{c}\}\}=\boldsymbol{\operatorname { m a x }}\{\max \{\mathrm{a}, \mathrm{b}\}, \mathrm{c}\}$
- Top element is 0 :
- $\max \{0, \mathrm{a}\}=\mathrm{a}$

## A Semilattice for Liveness

- Sets of live variables and the set union operation.
- Idempotent:
- $\mathrm{x} \cup \mathrm{x}=\mathrm{x}$
- Commutative:
- $\mathrm{x} \cup \mathrm{y}=\mathrm{y} \cup \mathrm{x}$
- Associative:
- $(x \cup y) \cup z=x \cup(y \cup z)$
- Top element:
- The empty set: $\varnothing \cup \mathrm{x}=\mathrm{x}$

## Semilattices and Program Analysis

- Semilattices naturally solve many of the problems we encounter in global analysis.
- How do we combine information from multiple basic blocks?
- Use the meet of all of those blocks.
- What value do we give to basic blocks we haven't seen yet?
- Use the top element.
- How do we know that the algorithm always terminates?
- Actually, we still don't! More on that later.

## A General Framework

- A global analysis is a tuple ( $\mathbf{D}, \mathbf{V}, \boldsymbol{\Lambda}, \mathbf{F}, \mathbf{I}$ ), where
- D is a direction (forward or backward)
- The order to visit statements within a basic block, not the order in which to visit the basic blocks.
- $\mathbf{V}$ is a set of values.
- $\boldsymbol{\Lambda}$ is a meet operator over those values.
- $\mathbf{F}$ is a set of transfer functions $f: \mathbf{V} \rightarrow \mathbf{V}$
- I is an initial value.
- The only difference from local analysis is the introduction of the meet operator.

## Running Global Analyses

- Assume that ( $\mathbf{D}, \mathbf{V}, \boldsymbol{\Lambda}, \mathbf{F}, \mathbf{I})$ is a forward analysis.
- Set OUT[s] = T for all statements $\mathbf{s}$.
- Set OUT[begin] = I.
- Repeat until no values change:
- For each statement $\mathbf{s}$ with predecessors

$$
\begin{aligned}
& \mathbf{p}_{1}, \mathbf{p}_{2}, \ldots, \mathbf{p}_{\mathbf{n}}: \\
& - \text { Set IN[s] }=\operatorname{OUT}\left[\mathbf{p}_{\mathbf{1}}\right] \wedge \operatorname{OUT}\left[\mathbf{p}_{2}\right] \wedge \ldots \wedge \operatorname{OUT}\left[\mathbf{p}_{\mathrm{n}}\right] \\
& \text { - Set OUT} \left.[\mathbf{s}]=\mathrm{f}_{\mathrm{s}} \mathrm{IN}[\mathbf{I N}]\right)
\end{aligned}
$$

- The order of this iteration does not matter.

## For Comparison

- Set $\operatorname{IN}[\mathbf{s}]=\mathrm{T}$ for all $\cdot \operatorname{Set} \operatorname{IN}[\mathbf{s}]=\{ \}$ for each statement $\mathbf{s .}$ statement s.
- Set IN[exit] to the set of variables known to be live on exit.
- Repeat until no changes occur:
- For each statement s:
- Set OUT[s] = $\operatorname{IN}\left[\boldsymbol{x}_{1}\right] \wedge \ldots \wedge \operatorname{IN}\left[\boldsymbol{x}_{n}\right]$ where $\boldsymbol{x}_{1}, \ldots, \boldsymbol{x}_{\mathrm{n}}$ are successors of $\mathbf{s}$.
- Set IN[s] = $\mathrm{f}_{\mathrm{s}}(\mathrm{OUT}[\mathbf{s}])$
- For each statement $\mathbf{s}$ of the form $\mathbf{a}=\mathbf{b}+\mathbf{c}$ :
- Set OUT[s] to set union of IN[x] for each successor $\boldsymbol{x}$ of $\mathbf{s}$.
- Set IN[s] to $(\mathrm{OUT}[\mathbf{s}]-\mathbf{a}) \cup\{\mathbf{b}, \mathbf{c}\}$.

## The Dataflow Framework

- This form of analysis is called the dataflow framework.
- Can be used to easily prove an analysis is sound.
- With certain restrictions, can be used to prove that an analysis eventually terminates.
- Again, more on that later.

## Global Constant Propagation

- Constant propagation is an optimization that replaces each variable that is known to be a constant value with that constant.
- An elegant example of the dataflow framework.

## Global Constant Propagation

## Global Constant Propagation

## Global Constant Propagation

## Constant Propagation Analysis

- In order to do a constant propagation, we need to track what values might be assigned to a variable at each program point.
- Every variable will either
- Never have a value assigned to it,
- Have a single constant value assigned to it,
- Have two or more constant values assigned to it, or
- Have a known non-constant value.
- Our analysis will propagate this information throughout a CFG to identify locations where a value is constant.

## Properties of Constant Propagation

- For now, consider just some single variable $\mathbf{x}$.
- At each point in the program, we know one of three things about the value of $\mathbf{x}$ :
- $\mathbf{x}$ is definitely not a constant, since it's been assigned two values or assigned a value that we know isn't a constant.
- $\mathbf{x}$ is definitely a constant and has value $\mathbf{k}$.
- We have never seen a value for $\mathbf{x}$.
- Note that the first and last of these are not the same!
- The first one means that there may be a way for $\mathbf{x}$ to have multiple values.
- The last one means that $\mathbf{x}$ never had a value at all.

## Defining a Meet Operator

- The meet of any two different constants is Not a Constant.
- (If the variable might have two different values on entry to a statement, it cannot be a constant.)
- The meet of Not a Constant and any other value is Not a Constant.
- (If on some path the value is known not to be a constant, then on entry to a statement its value can't possibly be a constant.)
- The meet of Undefined and any other value is that other value.
- (If $\mathbf{x}$ has no value on some path and does have a value on some other path, we can just pretend it always had the assigned value.)

## A Semilattice for Constant Propagation

- One possible semilattice for this analysis is shown here:

## A Semilattice for Constant Propagation

- One possible semilattice for this analysis is shown here:

This lattice is infinitely wide:

## Dataflow for Constant Propagation

- Direction: Forward
- Semilattice: Defined earlier
- Transfer functions:
- $\mathrm{f}_{\mathrm{x}=\mathrm{k}}(\mathrm{V})=\mathrm{k}$
(assign a constant)
- $\mathrm{f}_{\mathrm{x}=a+b}(\mathrm{~V})=$ Not a Constant (assign non-constant)
- $\mathrm{f}_{\mathrm{y}=\mathrm{a}+\mathrm{b}}(\mathrm{V})=\mathrm{V}$ (unrelated assignment)
- Initial value: $\mathbf{x}$ is Undefined
- (When might we use some other value?)
